Abstract

Background	Motor unit number estimation (MUNE) is a unique electrophysiological technique that was developed to determine a numeric estimate of the number of innervating axons. This technique can be used to determine the approximate number of motor neurons in a muscle or group of muscles.
Objective	To test the MUNE values according to subject's gender and hand dominancy in the normal population.
Methods	Healthy volunteers who had neither neuromuscular nor systemic/ metabolic disease, with normal neurological examination were studied. Ninety hands of 56 healthy volunteers (11 males and 45 females) with ages ranging from (24-58) years were included in the study. All had normal median nerve conduction studies. Manual incremental (INC) method and adapted multiple points stimulation (AMPS) method were performed for MUNE.
Results	Gender did not have an effect on the scores according to the two studied methods (p=0.054 by INC method and p= 0.700 by AMPS method). Hand dominancy also show no statistically significant difference of the scores of MUNE according to both studied methods (p=0.091) by INC method and (p=0.051) by AMPS method.
Conclusion	Incremental stimulation and adapted multiple point stimulation are reliable and easily applicable methods with same reproducibility in estimating motor units with no significant effect for subject gender or hand dominancy.
Keywords	Motor unit, motor unit number estimation (MUNE), incremental stimulation (INC) method, adapted multiple point stimulation (AMPS) method

List of abbreviations: AMPS = Adapted multiple point stimulation, APB = Abductor pollicis brevis muscle, CMAP = Compound motor action potential, CTS = Carpal tunnel syndrome, EMG = Electromyography, EP = Evoked potentials, INC = Incremental stimulation, MCP = Metacarpophalangeal joint, MNCS = Motor nerve conduction study, MU = Motor unit, MUNE = Motor unit number estimation, SNCS = Sensory nerve conduction study

Introduction

A motor unit (MU) is defined as a single anterior horn cell or brain stem motor neuron, its peripheral axon (which travels in a cranial or peripheral nerve), and each of the muscle fibers innervated by that axon. they are considered as the final common pathway of the motor system [1].

The numeric determination of numbers of MUs is described as motor unit number estimation (MUNE) [2]. MUNE provides determination of functional MU numbers quantitatively as the

most parallel to the real numbers and can be performed in various techniques [1].

The thought of estimating MUs was firstly mentioned by McComas in 1967. Estimating the functional MUN in a human muscle group in vivo has been facilitated by using computer-aided MUNE techniques. There have been at least 10 different MUNE techniques reported up till now and each of which has some advantages and disadvantages. There have not been so many studies directly quantifying the effect of hand dominancy or even the effect of gender on MUNEs although these electrophysiological techniques have been available [2-5].

This study aimed to determine the effect of subject gender and hand dominancy on estimated MUN in Abductor pollicis brevis (APB) muscle of healthy subjects using incremental stimulation (INC) and adapted multiple point stimulation (AMPS) methods

Methods

A cross sectional study was conducted at the Neurophysiology Unit at Al-Imamein Al-Kadhimein Medical City during a 4-month period (Nov. 2017 to Mar. 2018). The study was approved by the Institute Review Board of the College of Medicine, Al-Nahrain University. An ethical consent was taken from each participant to be enrolled in the study.

Subjects

The study was performed on 90 hands of 56 healthy volunteers with a mean age of 36.22±7.32 years (age range = 24-58 years). Eleven subjects were males (19.6%) and 45 were females (80.4%). Forty-nine subject (87.5%) were right-handed and only seven were left-handed (12.5%). The study excludes any subject with history of wrist fracture or surgery, carpal tunnel syndrome, cervical radiculopathy, hereditary or acquired peripheral neuropathy.

Healthy volunteers with neither Neuromuscular disease nor any systemic/metabolic disease were included in the study. All subjects were considered to be

moderately active for their respective age groups. Before the study, systemic and neurological examinations of subjects were made and if they had normal findings, conventional neurophysiological studies of median and ulnar nerves were performed and if these were also normal, MUNE studies by INC stimulation and AMPS techniques were carried on.

Instrumentation

The following were used for all electrodiagnostic testing:

Computerized Electromyography/ Evoked potentials (EMG/EP) machine (Cadwell, 8-channel electromyograph) supplemented with different types of electrodes including grounding electrode used to protect the subject against electrical hazard and to reduce stimulus artifacts and interference, stimulating surface electrodes was used to stimulate the nerves through the skin and surface recording electrodes.

Electrophysiological studies

For each subject, conventional neurophysiological studies (sensory, motor and F wave studies) were performed to exclude peripheral neuropathy. MUNE of both APB muscles using both INC & AMPS methods were performed.

Sensory nerve conduction study

An antidromic method was used for sensory nerve conduction study (SNCS) determination, in which, the nerve was proximally stimulated from the trunk and the evoked activity was distally recorded from a finger. The parameters studied were the sensory latency (SL), sensory nerve action potential (SNAP) amplitude from peak to peak and sensory nerve conduction velocity (SNCV) measured by dividing the conduction distance (d) by the SL and measured in meter/second (m/sec) [6].

Motor nerve conduction study and F-wave

The motor nerve was simulated at two points along its course, by applying stimuli at the

distal and the proximal sites of the nerve and recording from the muscle innervated by that nerve. The parameters studied were distal motor latency (DML). Motor nerve conduction velocity (MNCV) measured by dividing the distance between the two stimulation points over the difference between the latencies of the recorded responses ensuring both compound muscle AP (CMAP) configurations must be similar in addition to F wave latency measured from the stimulus artifact to the beginning of the evoked potential [6].

Motor-unit number estimation
MUNE values are calculated from the ratio:

$$\frac{\text{maximal compound muscle action potential (CMAP) amplitude or area}}{\text{average single motor unit potential (MUP) amplitude or area}}$$

MUNE test was performed using a manual INC method. MUNE was recorded from a surface-active recording electrode placed over the motor point of the APB with the reference over the metacarpal phalangeal (MCP) joint of the thumb. The median nerve was stimulated at wrist by Cadwell electrical stimulator, at 8 cm proximal to the active electrode. For accurate nerve stimulation, the exact site of stimulation was marked by pin at wrist prior to stimulation. A built-in MUNE analysis program in the Cadwell EMG device was used, and the maximum M response was first obtained by increasing stimulation intensity and a maximal CMAP is recorded. Next, the display sensitivity is raised to 100–200 µV/div to help visualize low amplitude steps in the response envelope. The stimulus intensity is lowered to 3–10 mA in order to activate the first axon, indicated by an all-or-none response. By small increases in stimulation intensity, an envelope of responses is obtained with 8–10 discrete steps before the increments in the envelope become indistinguishable. The number of steps is divided into the peak to-peak amplitude of the envelope to determine the average amplitude of each step.

This average value represents the average single MUP (S-MUP), and is used to calculate the MUNE value (figures 1 and 2) [7].

Adapted multiple point stimulation (AMPS) method
Multipoint incremental MUNE method with the Shefner modification is a noninvasive, easy to perform method with high reproducibility [7,8].
By stimulating the nerve at many sites, this technique yield data from MUs with different morphologies. The recording electrode was placed on the belly of the APB muscle and a maximum CMAP was obtained by applying a supramaximal stimulus.
Median nerve of the right and left hand was studied. Recording electrodes were placed on the median nerve innervated APB muscle, using the standard belly tendon method. The MUNE program recorded the maximum CMAP amplitude obtained. Then display sensitivity was raised to 100–200 µV/div to help visualize low amplitude steps in the response envelop and the stimulus intensity was lowered to 3–10 mA in order to activate the first axon, indicated by an all-or-none response. Again, by small increase in stimulation intensity, an envelope of responses is obtained with 3-5 discrete steps before jumping to the next site.

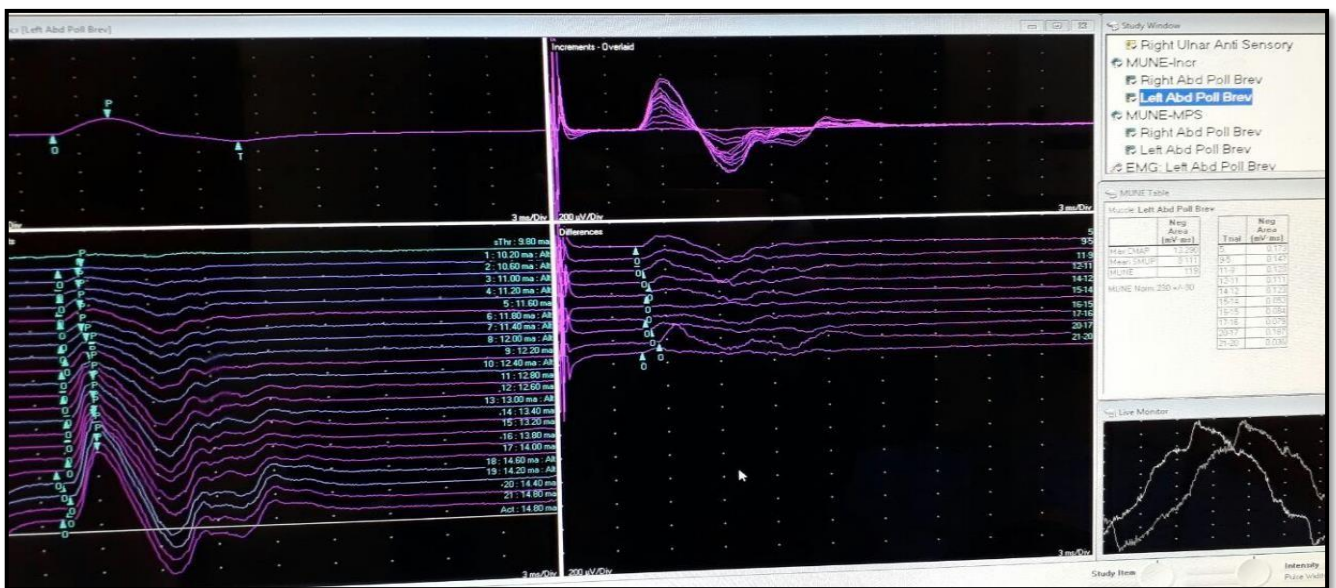

Figure 2. A photographic picture. of Cadwell EMG screen during incremental MUNE study

Using standard 3-site motor conduction program traces were obtained and superimposed. Three stimulus locations were used for the median nerve; 2 cm proximal to the wrist crease, 4 cm proximal to the first stimulation site, and in the cubital fossa. Optimum stimulus location was determined using a submaximal stimulus and moving the stimulator to evoke the greatest response.

Three responses were obtained at each stimulation site with each response of 25 μV incremental amplitude. The negative peak amplitude of the third response was recorded. Stimulation at the second and third location was identical to the first location. Once the sample collection was complete, we reviewed all tracings for potential repeating MUs (so that they were not included more than once). Using

standard 3-site motor conduction program traces were obtained and superimposed (figure 3) [5] The test last about 30 minutes for each subject.

Statistical analysis

The statistical analysis was obtained using statistical package of social sciences (SPSS) version 23 software and Microsoft Office Excel 2016.

All data were expressed as mean ± SD. Paired t-test was used to compare the dominant and non-dominant side and between males and females. P-value of 0.05 or less was considered significant.

Results

This study found that MUNE values of APB muscles by both techniques are higher in male group than in female (but not statistically significant).

Considering the hand dominancy, we found that the non-dominant hand APB muscle contains higher MUNE value that is 214.74±50.18 by INC. method and 272.35±68.49 by AMPS method for non-dominant APB and 196.18±49.2 by INC. method and 244.82±54.27 by AMPS method for dominant APB muscle- as shown in tables 1 & 2.

Table 1. MUNE value of the APB muscles in female and male subjects by INC and AMPS methods (unpaired t test)

MUNE method	Females N=67 Mean ± SD	Males N=23 Mean ± SD	P value
INC method	197.38±47.15	226.44±56.11	0.054
AMPS method	254.11±63.58	259.67±51.69	0.700

MUNE = motor unit number estimation, INC= incremental stimulation method, AMPS = Adapted multiple point stimulations method, ± SD = standard deviation.

Table 2. MUNE value of APB muscles of the dominant and non-dominant hands (unpaired t test)

MUNE method	Dominant hand N=56 Mean±SD	Non-dominant hand N=34 Mean±SD	P value
INC method	196.18±49.2	214.74±50.18	0.091
AMPS method	244.82±54.27	272.35±68.49	0.051

MUNE = motor unit number estimation, INC= incremental stimulation method, AMPS = Adapted multiple point stimulations method, ± SD = standard deviation.

Correlation of two MUNE methods

The above data denotes - no significant deference in MUNE values between INC and AMPS techniques. As seen in figure 4, a strong - positive correlation between values obtained by both methods was found (r=0.769 and p < 0.001).

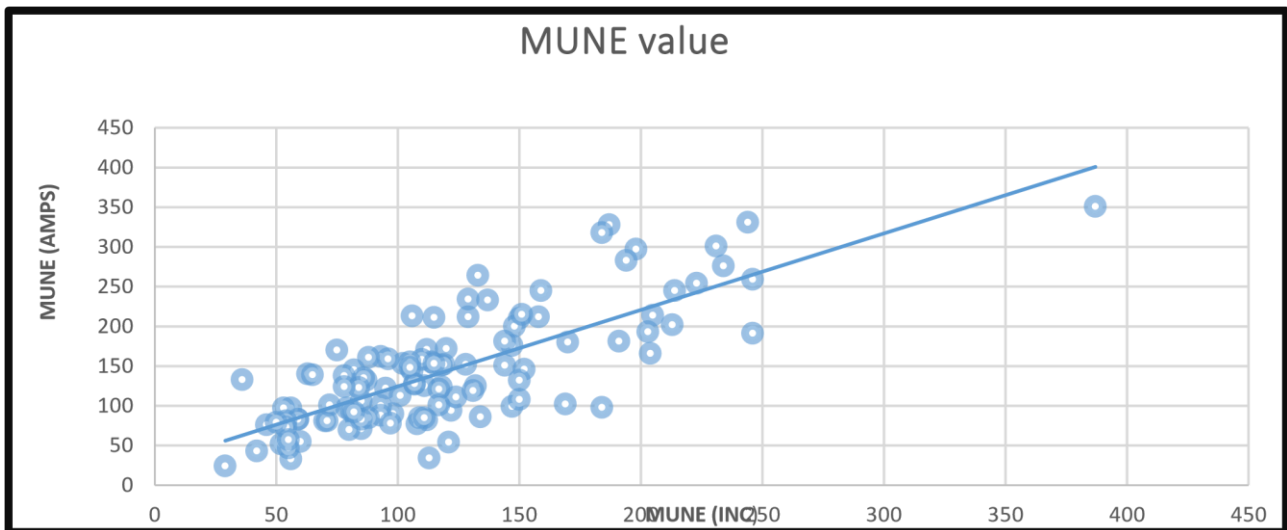

Figure 4. Correlation of INC and AMPS methods for MUNE

Discussion

For now, there have been many available MUNE techniques share in common studying the features of MUs in an attempt to determine quantitively the functional MUN - as the most similar to the real numbers. All the

techniques have been developed based on manual incremental method [9].

The aim of MUNE methods is to calculate the number of fibers in a muscle almost correctly and relative to the real numbers. Certainly, the most accurate way of this is to estimate fibers histologically. Studies dealt with correlation between histological and electrophysiological studies are scarce [9,10]. In general, according to the test reliability, the necessary period for completing study, easiness, obtaining data parallel to disease and sufficiency in determining progression of disease, none of these different methods is superior to each other [11].

Manual INC and AMPS methods were used in this study. Results of the study revealed quite similar values in standard conditions between the two methods. although practically we prefer to use incremental stimulation method since it easier to stimulate median nerve at wrist in comparison with three stimulation sites for median nerve in AMPS.

Furthermore, the study demonstrated that gender has no significant effect on MUNE values (though the results show that MUNE in males higher than that of females but statistically not significant). This may be explained by the more muscular components of male body or hormonal differences, increasing sample size is mandatory to study this difference. These results are similar to that reported by Yerdelen et al. in 2006 who state that gender had no effect on MUNE value although his results show higher values in male than females but statistically not significant [1].

Also, we found that MUNE values of median innervated APB muscle by both techniques are not statistically significantly different according to hand dominancy (even though the results show higher values in non-dominant hands but still not significant). The current data were comparable with those reported by Li et al. who state that there was no statistically significant difference between both dominant and non-dominant hand regarding first dorsal interossi (FDI) and thenar muscles regardless his results show high motor unit number index

(MUNIX), lower motor unit size index MUSIX in non-dominant hands for both muscles [12,13].

Handedness is associated with brain lateralization. Asymmetrical excitability in the corticospinal system has been observed in many researches with transcranial magnetic stimulation [14,15]. Contradictory evidence was also reported showing no significant influence of handedness on motor evoked potentials [16]. The neural mechanisms underlying handedness is not fully understood yet. Regardless of neural origins of handedness, this study examined the MUNE estimations in dominant and non-dominant hand muscles. The MUNE values from bilateral hand muscles were within the range of previously reported reference values [3,13,17]. No significant difference in MUNE values was observed between the dominant and non-dominant hands for the thenar muscles, implying that the population of MUs or spinal motor neurons may not be associated with handedness [13].

In contrast to investigations on the lateral asymmetry in the central nervous system, aspects related to lateral asymmetry of the peripheral nervous system have been relatively less studied. By applying the MUNE technique, a previous study observed that the number of motor units of the APB muscle was higher for the non-dominant hand than the dominant hand muscles [18]. So higher sample size study is recommended to clarify this association.

The non-significant difference in MUNE results obtained by INC and AMPS methods in this study denotes that both are similarly reproducible and are equally effective and none of them was superior to the other which is in accordance with the other researchers as Xu et al. who stated that both MUNE methods are similarly reproducible and are equally effective in in estimating motor units and their reduction with aging and ALS patients [17].

In conclusion the present study revealed that the gender of subjects or hand dominancy did not affect MUNE value, both INC and AMPS techniques are easily applicable, similarly reproducible and are equally effective MUNE methods.
